

Magnetoencephalography (MEG)

Frederick Carver PhD
MEG Core Facility NIH

Our CTF system has 275 radial gradiometers, and 30 reference sensors (also EEG).

Signal Source

The long apical dendrites of cortical pyramidal cells are the theoretical source of MEG signals

Up to 10,000 parallel cells need to be active to produce measurable fields outside the head

A typical evoked field is on the order of 100 femto Tesla

(1fT = 10^{-15} T)

Comparison to EEG

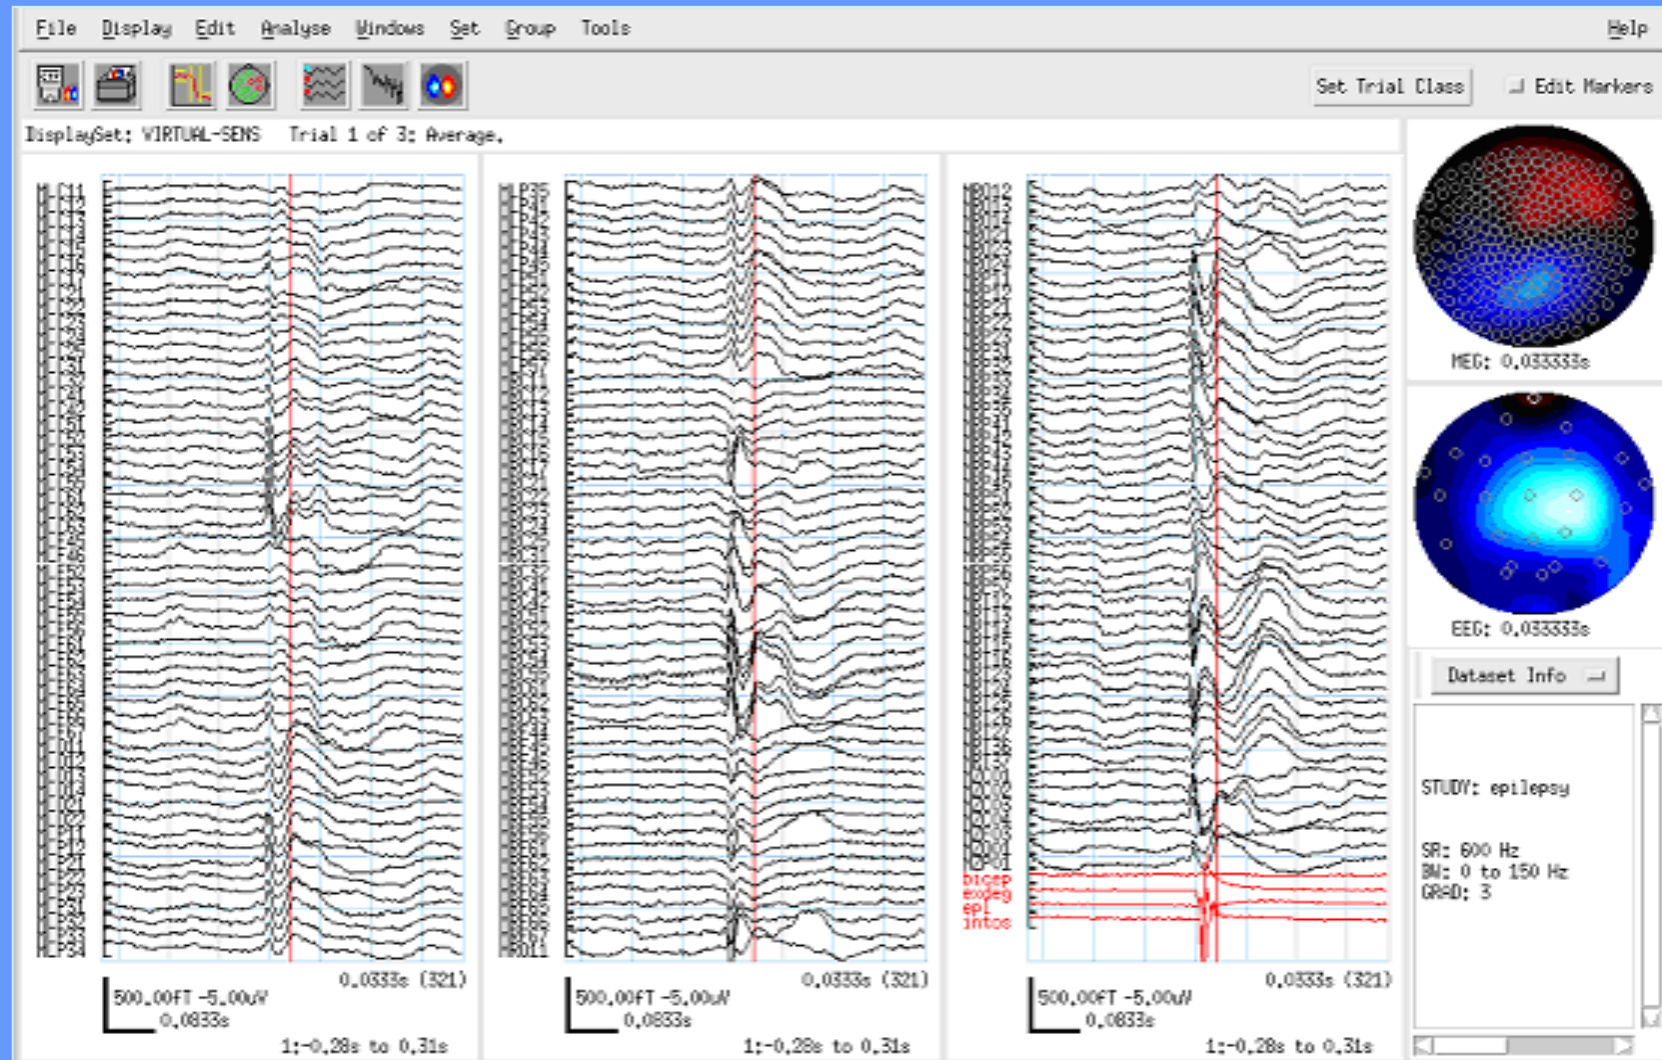

Magnetic fields pass through the skull without interference

Volume conduction distorts EEG signals making source reconstruction difficult

Some sources may be harder to see with MEG because of orientation, or cancellation. e.g. SMA

MEG Example

Epileptic spike associated with muscle twitch

Sato et al.,
NINDS

Time Series Analysis

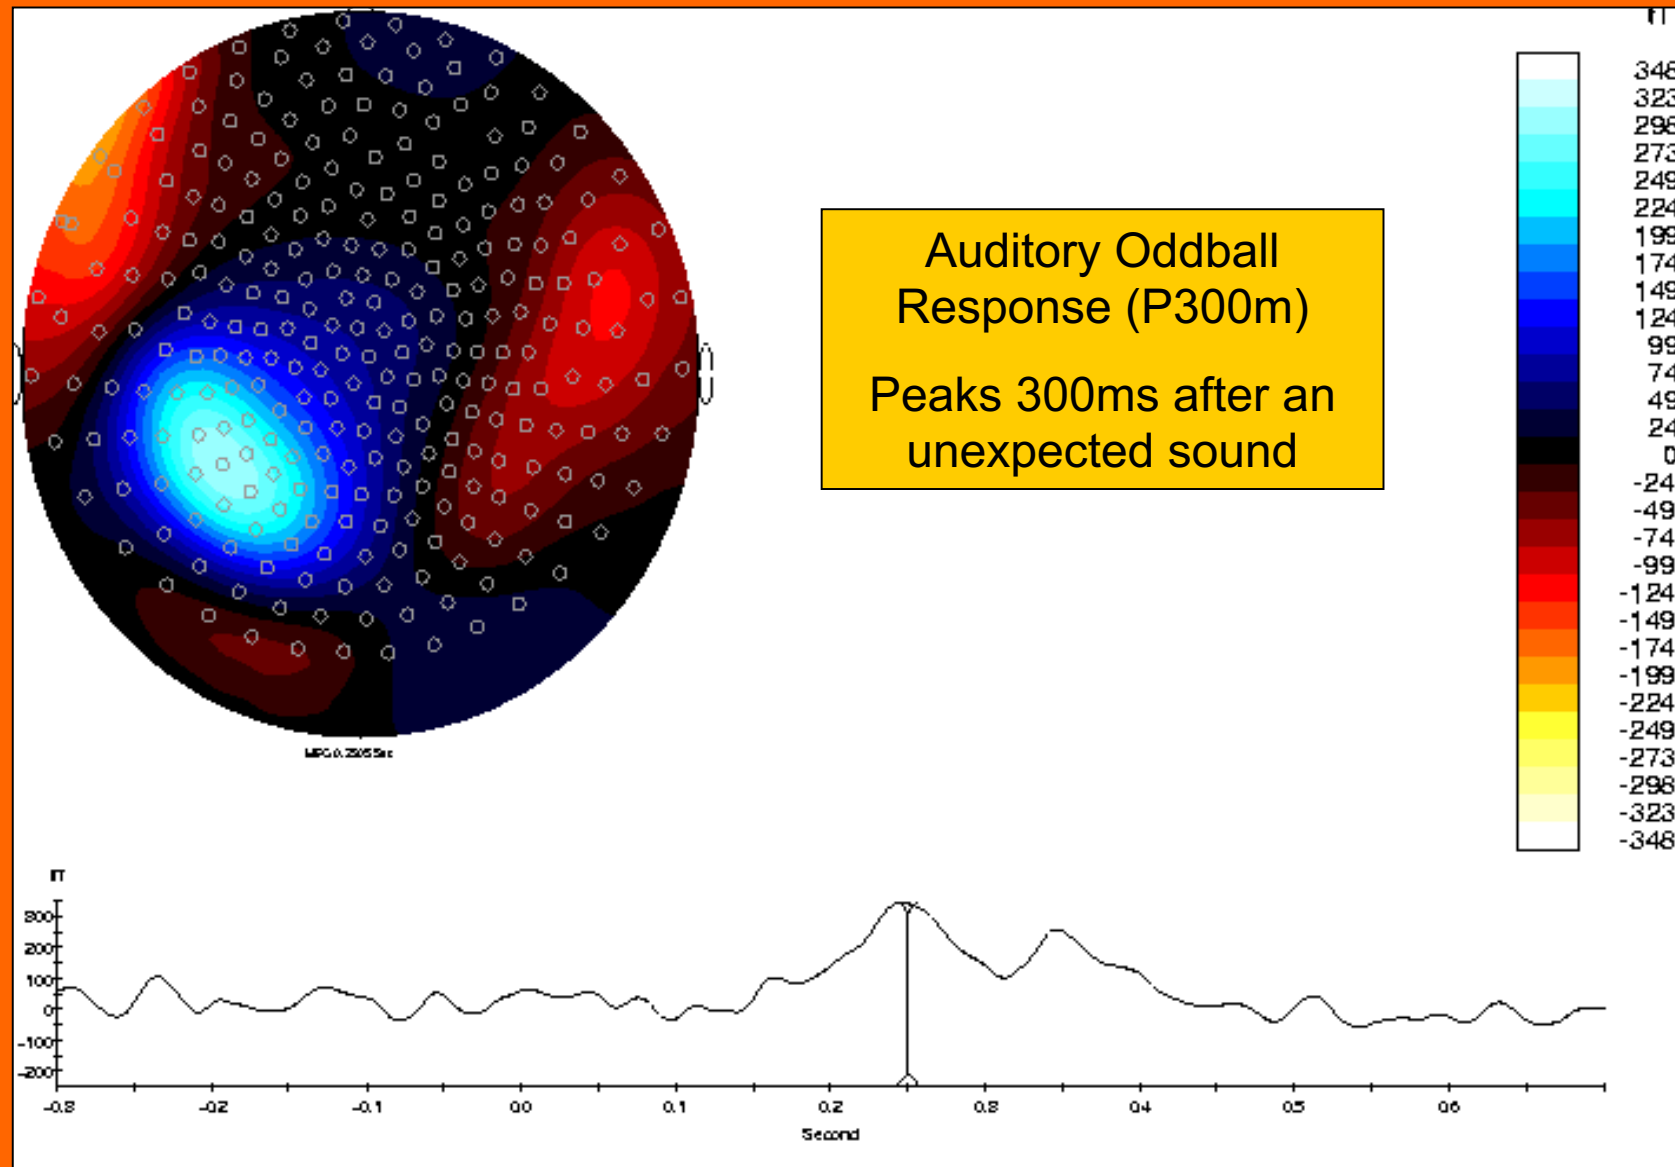

What are we looking for?

- Individual spikes or complex waveforms
e.g. epileptic spike, sensory evoked response
- Oscillations at particular frequency bands
e.g. theta (4-8Hz), alpha (8-13Hz), beta (14-30Hz),
gamma (30-50Hz)

Signal Averaging (Evoked/Event-related Fields)

- Average MEG time segments from similar stimuli/responses
- Quantify amplitude and/or peak latency of resulting ERFs

Time-frequency Analysis

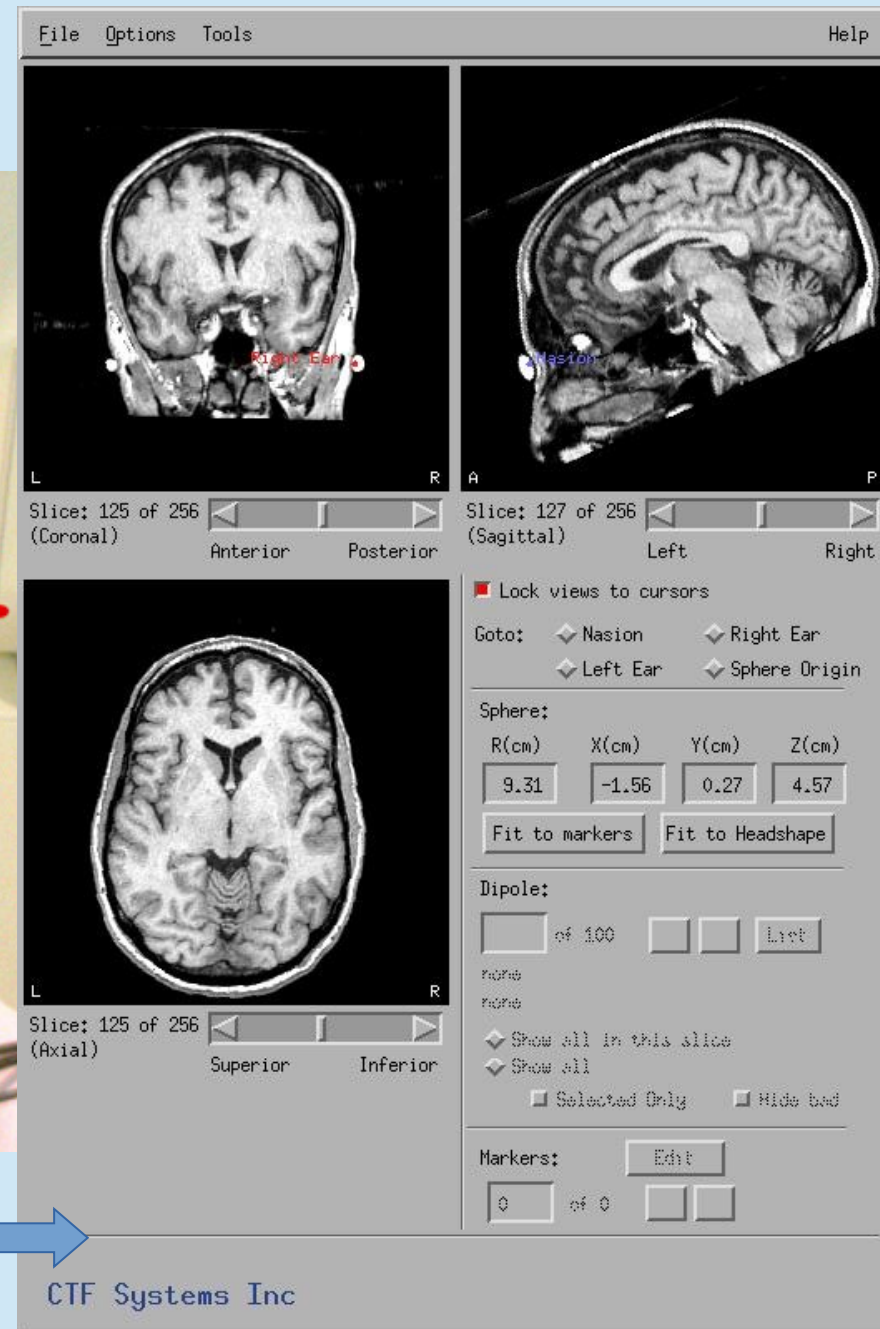

Evoked Response to series of five clicks separated by 250ms

How do we estimate the source of the MEG signals?

The coil locations are then marked on an MRI for co-registration

Dipole Fit

Find the one or more sources that best fit data at single time point

SAM (Synthetic Aperture Magnetometry)

- Produces whole brain estimates of source power for specified time window and frequency band
- Creates a spatial filter (beamformer) for each voxel to block out activity from other locations
 - Not good for correlated sources
 - Can generate 'virtual channels' at each voxel
- Subject group analysis can be conducted with AFNI or other fMRI software

Projection of Source
onto Sensors

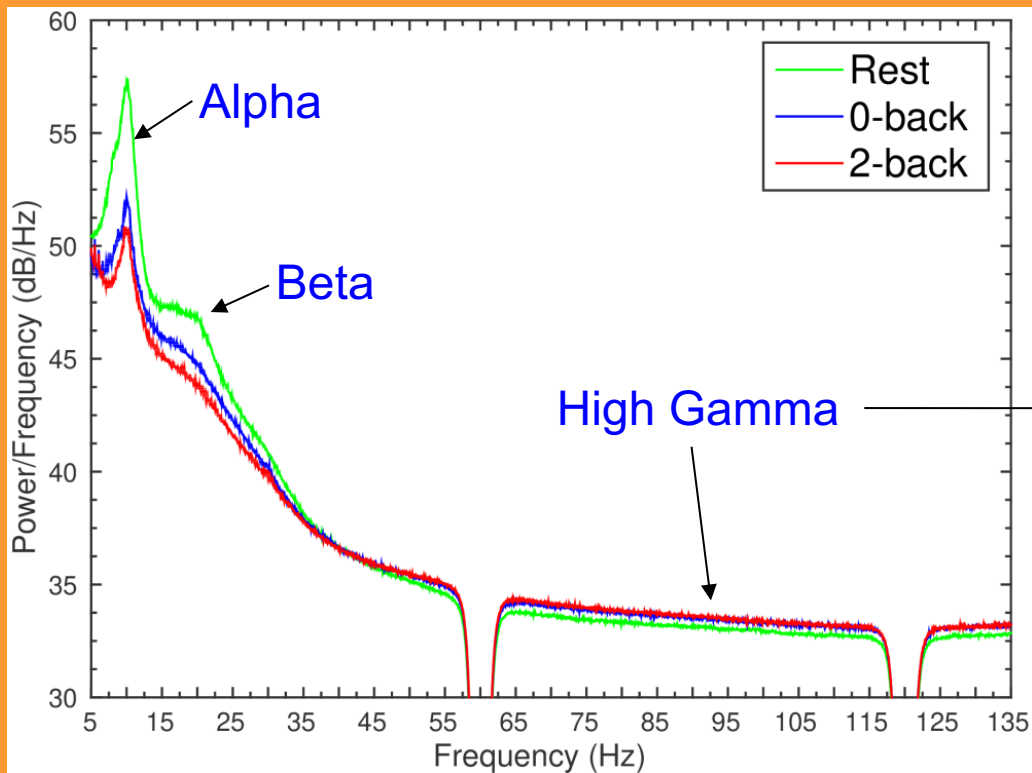

Spatial Filter

Example of SAM Analysis for an N-back working memory task with resting data used as a baseline

Power Spectra used to determine frequency bands for SAM Analysis

Red = $2 > 0$

'synchronization' ?

Blue = $2 < 0$

'desynchronization' ?

High Gamma

MEG and fMRI

2-back vs 0-back, same 12 subjects

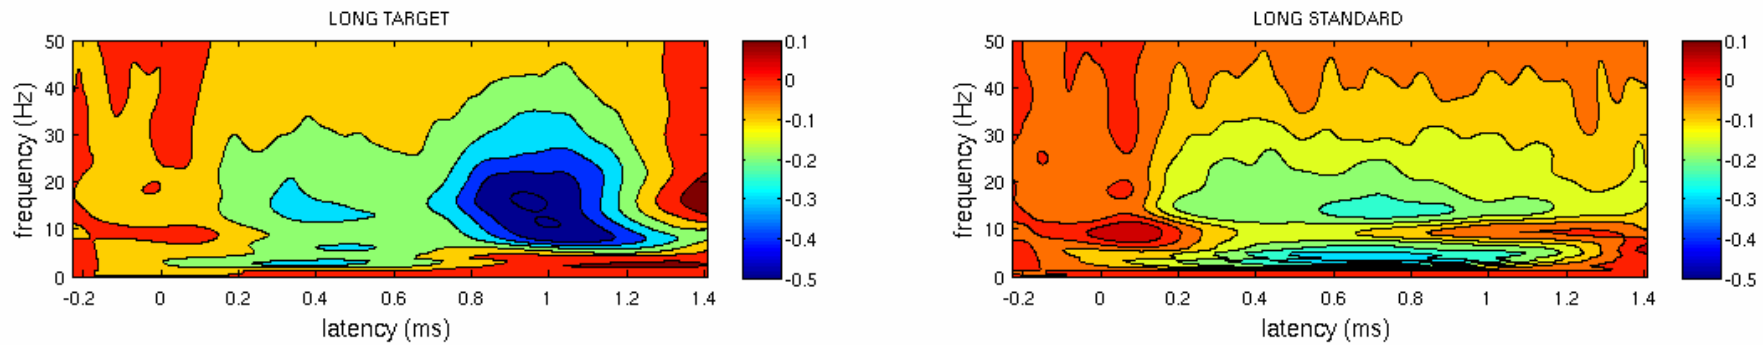

SAM, 500 msec window centered on response, Beta desynchronization

SPM T map 2b>0b {SPM99 $t \sim 4.0$;
 $Z_{\text{eq}} \sim 3.10$, $p \sim 0.001$, $k > 10$ }

Localization not as precise as fMRI, but enhanced temporal resolution. Example from a tone duration experiment

Long non-target tone, < 2s in a loop

Carver et al., 2012

Deep Sources

Long deemed to be impossible to observe, but really just a matter of signal-to-noise. Modern MEG systems make it possible.

Cerebellum

Amygdala

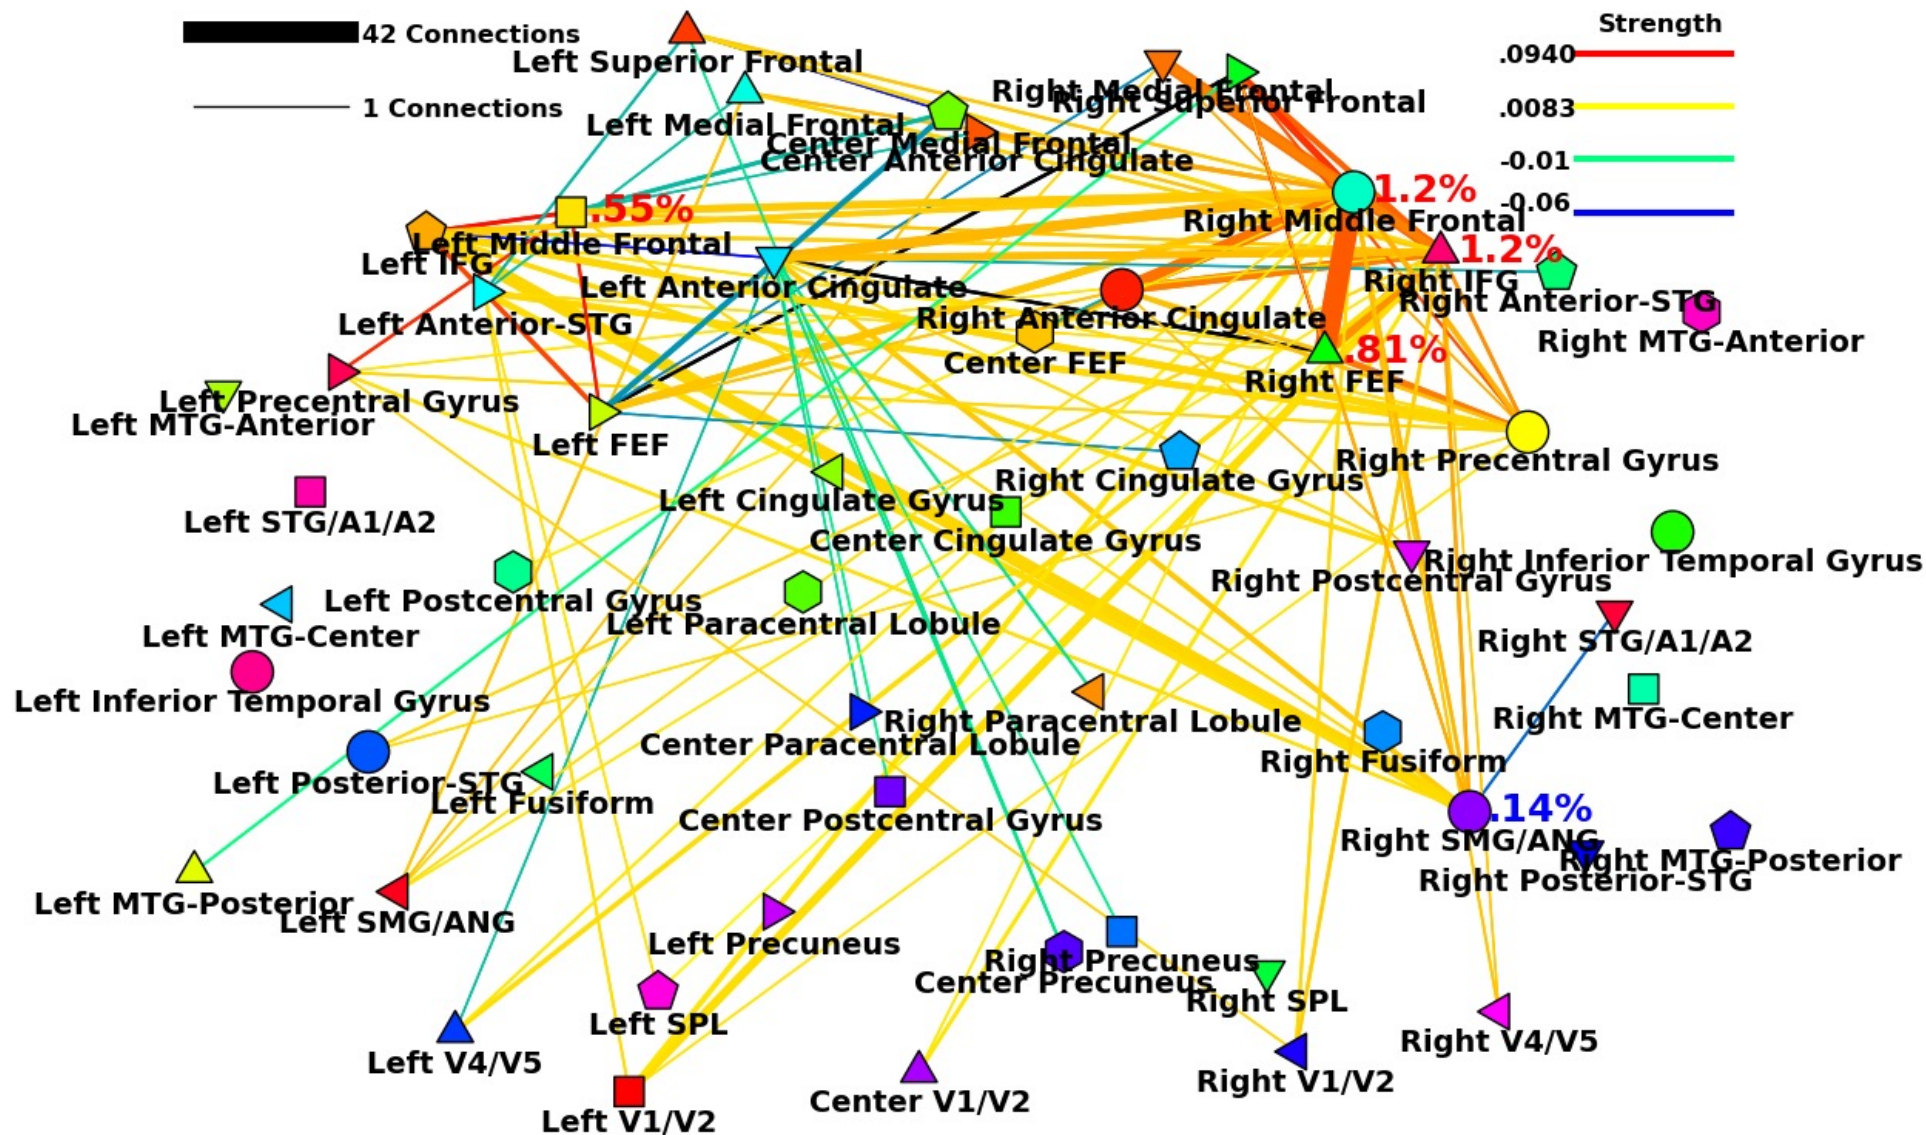

Hippocampus

Connectivity?

- as yet no predominant method or theoretical underpinning

Power envelope correlation on virtual channels, N-back
– Tyler Ard dissertation

Coherence, same data

Clinical Research Applications

What are the observable signs of altered cortical and subcortical function in MEG?

- Delayed or reduced amplitude evoked responses
- Local oscillatory power changes
- Long range communication differences (conduction delays; lack of synchrony; connectivity patterns)
- Complex measures? (signal-to-noise ratio; entropy)

Evidence for aberrant neuromagnetic activation in patient populations

Magnetoencephalographic Gamma Power Reduction in Patients with Schizophrenia During Resting Condition

Daniel R. Weinberger,² and Richard Coppola^{1,2*}

◆ Human Brain Mapping 30:3254–3264 (2009) ◆

Clinical Research Applications

What can be associated with observed differences?

- Genotype / Genetic risk
- Neurotransmitter levels
- Models of network dynamics
- Performance differences / Behavioral phenotypes
- Diagnostic criteria / Symptom severity
- Neuropsychological testing
- Medication / Therapeutic response
- Training / Cortical stimulation

Normal Controls, 2-back activation, beta band

MEG and Pharmaceutical Response

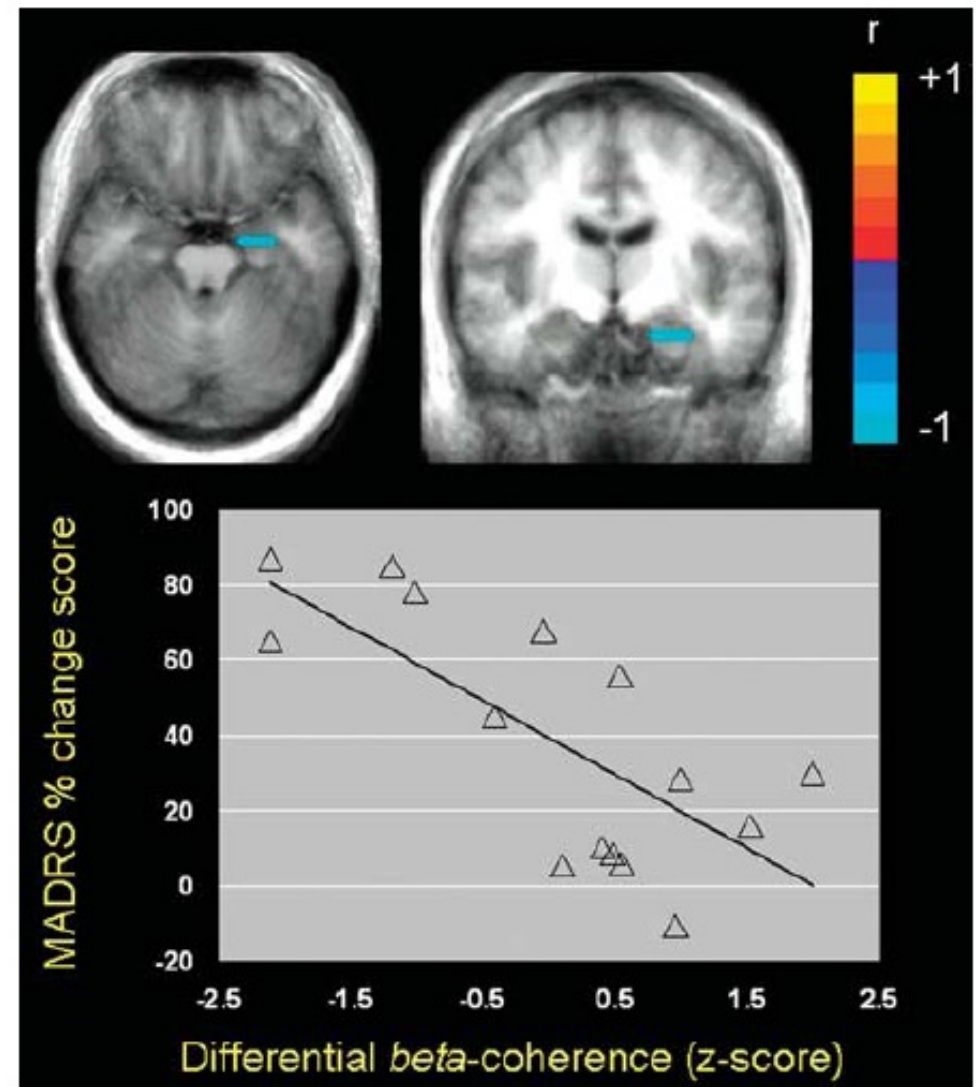

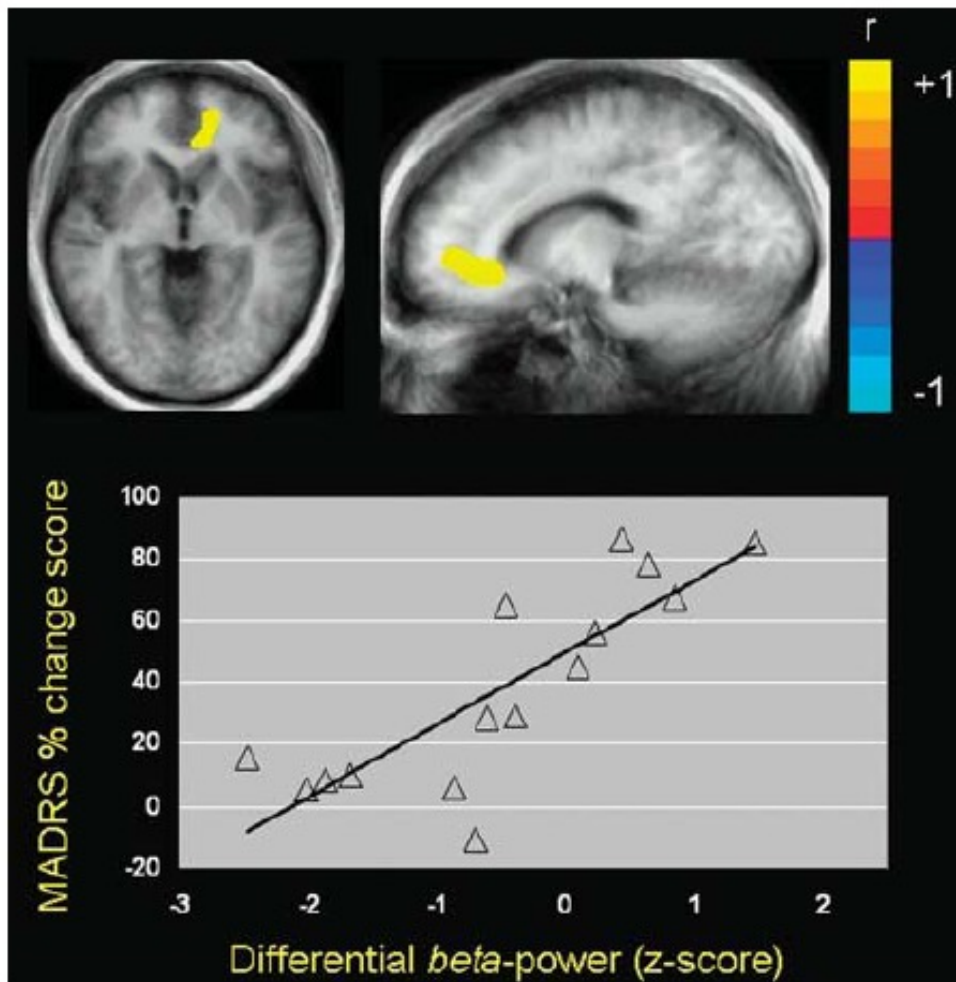

Figure 1 Pearson correlation between beta desynchronization in the anterior cingulate cortex (ACC) and change in depressive symptoms 230 min after ketamine infusion for the 2-back vs 1-back comparison in patients with MDD (ACC peak $x = -15$, $y = 45$, $z = -1$ mm; coordinates expressed according to the stereotaxic atlas of Talairach and Tournoux (Talairach and Tournoux, 1988)). These coordinates localize to the pregenual portion of the ACC, although the cluster of voxel t -values

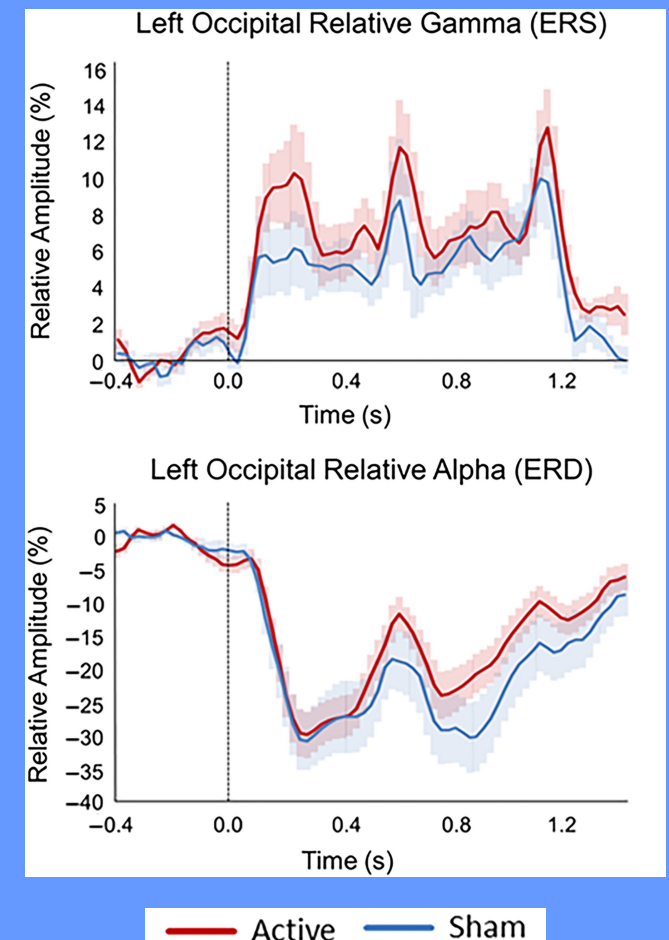

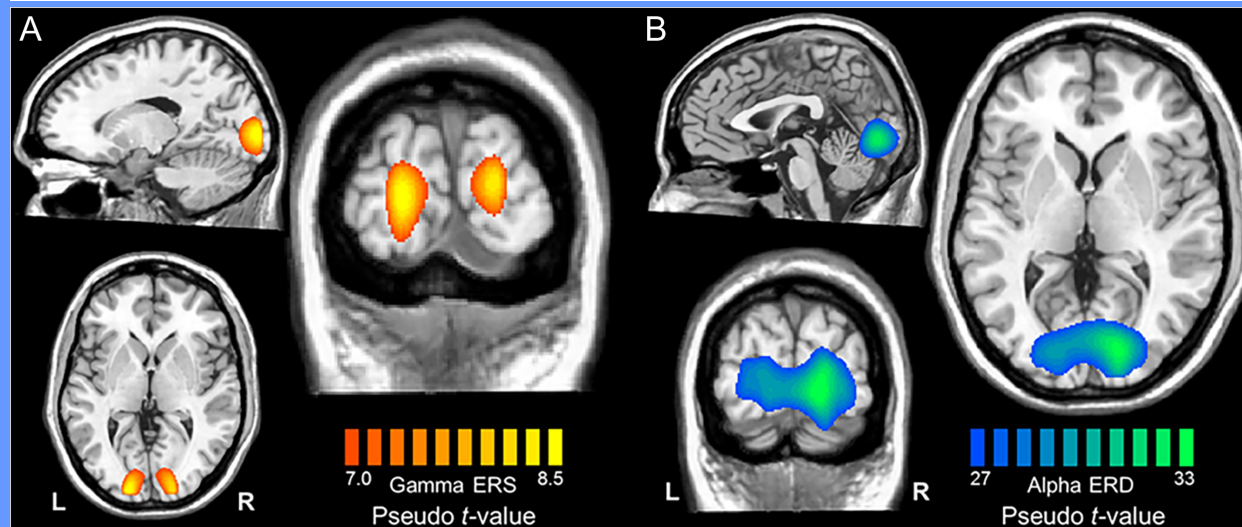

Figure 2 Pearson correlation between differential source coherence of the pgACC with the left amygdala and change in depressive symptoms 230 min after ketamine infusion for the 2-back vs 1-back comparison in patients with MDD (left amygdala peak: $x = -30$, $y = -7$, $z = -16$ mm;
