Mediation analysis for fMRI-based pain assessment

Lauren Atlas
July 20, 2015

Mediation analysis for fMRI

- ✓ Assess dynamic relationships between experimental manipulation, brain, and behavior
- ✓ Voxelwise mixed effects (multilevel) path analysis
- ✓ Identify candidates for causal inference
- ✓ Effective connectivity analysis
- ✓ Identify sources of individual differences in pathway strength

Roadmap

- Introduction (Pain imaging)
- Mediation analysis for fMRI
 - Single level mediation
 - Multi-level mediation
- Brain mediators of the effects of heat on pain
- Brain mediators of expectancy effects on pain

PAIN

PAIN

*“An unpleasant **sensory and emotional** experience associated with **actual or potential tissue damage**, or described in terms of such damage.”*

–IASP Task force on taxonomy, 1994

“The pain matrix”

Sensation

Lateral thalamus

SI

SII

High vs Low intensity stimulation

Five studies, N = 114 Posterior Insula

FWE, $p < .05$

Affect

Medial thalamus

Anterior cingulate

Anterior insula

Atlas et al. (2010), *JNeurosci*

PAIN

“Pain is always subjective.”

*“Activity induced in the nociceptor and nociceptive pathways by a noxious stimulus is not pain, which is **always a psychological state**, even though we may well appreciate that pain most often has a proximate physical cause.”*

–IASP Task force on taxonomy, 1994

Nociception

PAIN

Noxious stimulus

Subjective pain

1. Which brain pathways mediate the effects of noxious stimuli on subjective pain?

How Painful?

I. Which brain pathways mediate the effects of noxious stimuli on subjective pain?

II. Which pathways mediate expectancy effects on pain?

Roadmap

- Introduction (Research questions)
- **Mediation analysis for fMRI**
 - **Single level mediation**
 - Multi-level mediation
- Brain mediators of the effects of heat on pain
- Brain mediators of expectancy effects on pain

Mediation

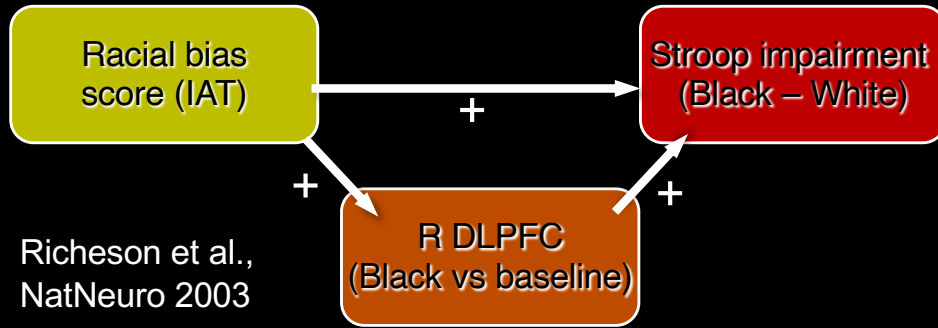

Woodworth, 1928

Provides a formal test of whether the relationship between input (S/X) and output (R/Y) can be explained by a mediator (M; brain activity)

Single level mediation in neuroimaging

Interpretation:

Those individuals high in X show greater responses to M, and that in turn leads to effects in Y. If you could disrupt M, X effect on Y would be reduced or abolished.

Demonstrating Mediation

Reduced model, without mediator

$$y = cx + e_y$$

Full model, with mediator

$$m = ax + e_m$$

$$y = bm + c'x + e'_y$$

Baron and Kenny (1986) – conjunction of 3 effects:

- 1) *c* effect: There is a relationship to be mediated
- 2) *a* effect: initial variable related to mediator
- 3) *b* effect: mediator relates to outcome, controlling for initial variable

And, if *m* is a complete mediator, $c' = 0$

Demonstrating Mediation

Reduced model, without mediator

$$y = cx + e_y$$

Full model, with mediator

$$m = ax + e_m$$

$$y = bm + c'x + e'_y$$

Does *m* explain some of the *x*-*y* relationship (*c*)?

$$c - c' = a * b$$

Counterfactual: If we were to prevent *m* from varying, the effect of *x* on *y* would be reduced or absent.

Interpreting mediation

- Individuals higher in [X] show greater [Y] because of changes in [M]
- The effect of [X] on [Y] can be explained by individual differences in [M]
- Group differences in [Y] are due to group differences in [M]

Interpreting mediation

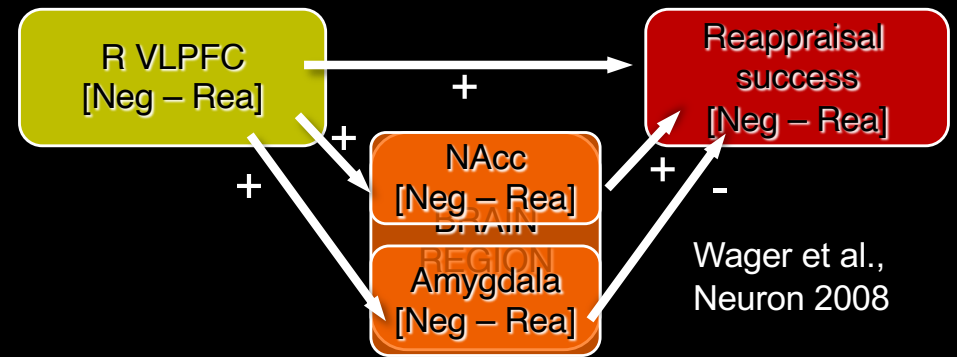

Stronger inferences about directionality if variables are randomly assigned, separated in time

Strongest inference when you can experimentally manipulate X AND M (e.g. using TMS)

- see Holland, Rubin

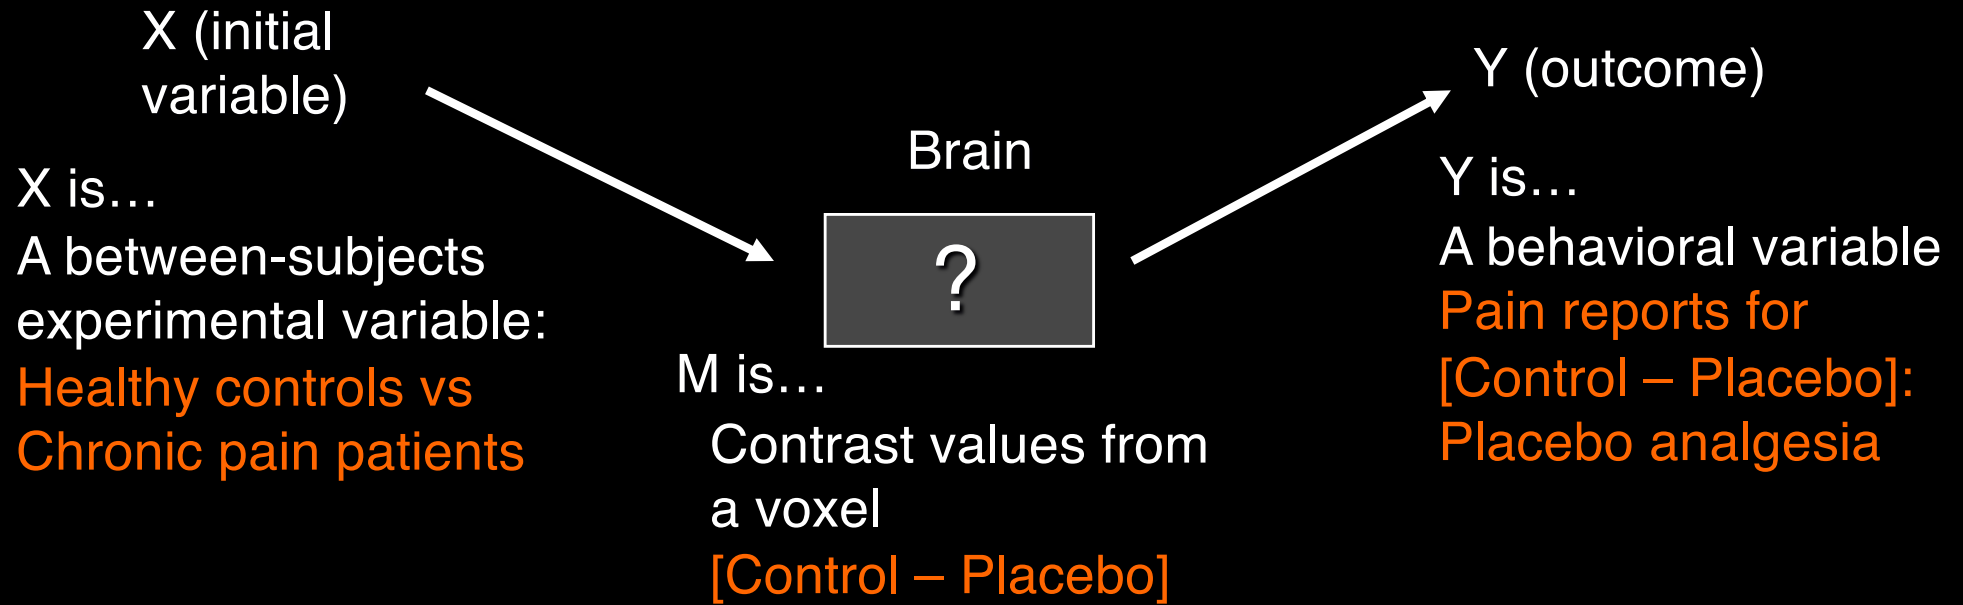

Single level mediation in neuroimaging

Voxel-wise mediation
effect parametric
mapping (MEPM)

“Mediation Effect Parametric Mapping”

“Mediation Effect Parametric Mapping”

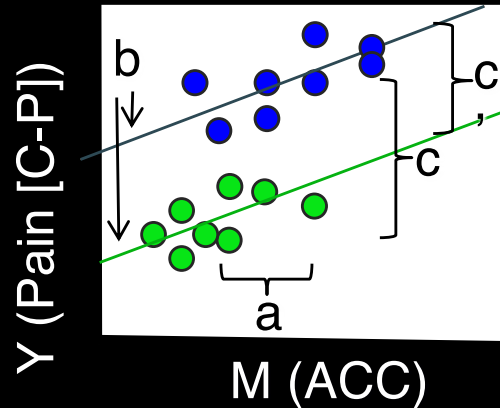

($a*b$) is a test of whether group differences in placebo effect are explained by brain activity (c-c')

Mediation vs. Conjunction

- X
- Controls
- Chronic pain patients

Conjunction without mediation

Conjunction and Mediation

Path c: Group difference in placebo effects on pain

Path a: Group difference in placebo effect on ACC

Path b: Brain-behavior correlation in ACC, controlling for group

Path c':

Left: Group difference in placebo analgesia even when you account for path *b*: No mediation, $c - c' = 0$

Right: Group diffs in ACC responses entirely explain group diffs in placebo analgesia; Full mediation, $c' = 0$

Testing the significance of $a*b$

■ Sobel test

Aroian, L. A (1944)

$$Z = \frac{ab}{b^2 se(a)^2 + a^2 se(b)^2 + se(a)^2 se(b)^2}$$

- Assumes a , b are normally distributed
- Usually conservative (p-values higher than needed)

• Bootstrap test :

Efron, 1994; Shrout & Bolger, 2002;
Preacher & Hayes, 2004

Histogram of bootstrapped
Indirect ($a*b$) effects

Roadmap

- Introduction (Research questions)
- **Mediation analysis for fMRI**
 - Single level mediation
 - **Multi-level mediation**
- Brain mediators of the effects of heat on pain
- Brain mediators of expectancy effects on pain

Mediation analysis:

Single vs multilevel mediation

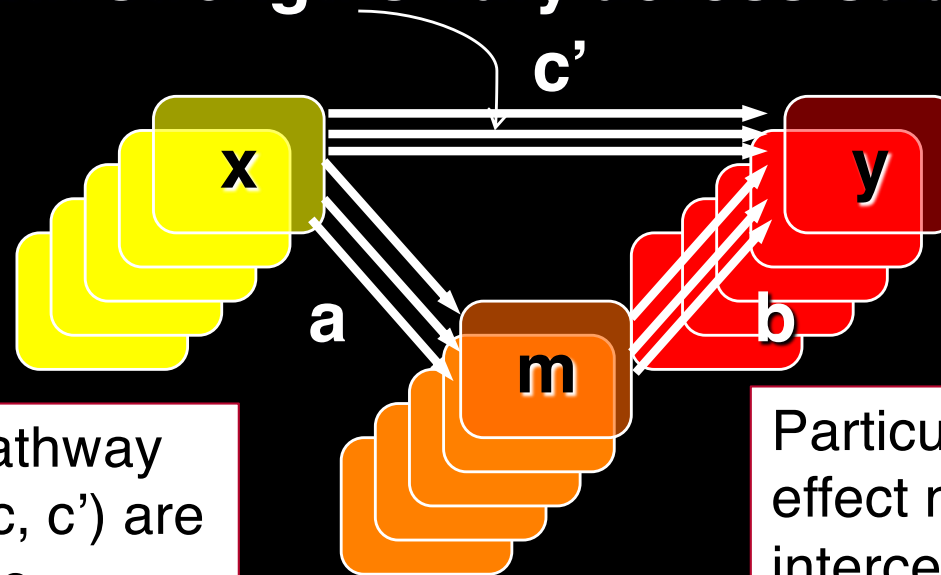

~~$c = a * b$~~ Rather than one value per subject
 $c = a * b + cov(a, b)$

model the entire timeseries, assess

Kenny, Korchmaros, & Bolger (2003)

within-subjects effects

Path strengths vary across subjects

Observations on each variable are nested within subjects

Subject-level pathway strengths (a, b, c, c') are random variables

Particular type of mixed-effect model: Random intercept, random slope model, with subject as random effect

Example: fMRI experiment

Which brain pathways mediate the effects of temperature (noxious heat) on pain?

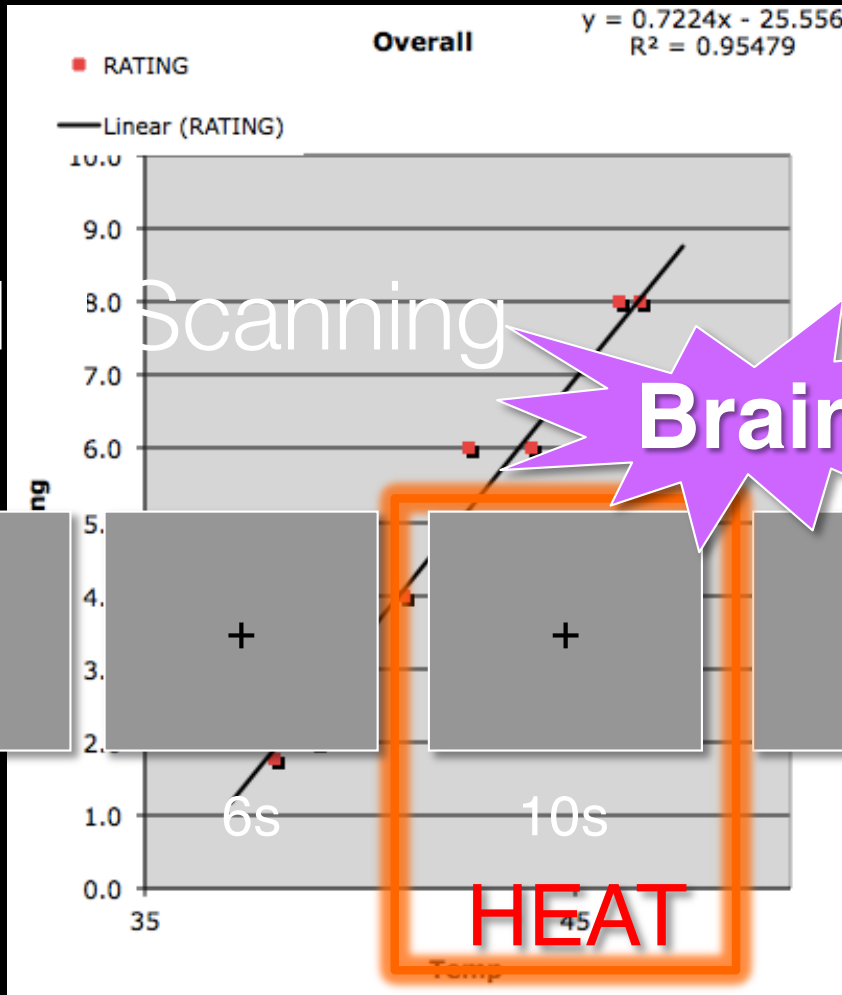

Atlas et al., 2014, Pain

Design

1. Adaptive calibration:

2. fMRI Scanning

- Warmth (Level 1)
- Low Pain (Level 3)
- Med Pain (Level 5)
- High Pain (Level 7)

IV

Design

1. Adaptive calibration:

Warmth (Level 1)

Low Pain (Level 3)

Med Pain (Level 5)

High Pain (Level 7)

2. fMRI Scanning

Important! # of observations

- Within each subject, need **equal observations of X, M, and Y**
- Easy if individual differences or 3 brain regions (connectivity)
- Here, each trial has:
 - 1 temperature (X)
 - 1 rating (Y)
 - ~10 seconds of pain, plus HRF!

Voxelwise single trial analysis

1. Fit basis functions trial-by-trial

2. Es

Network 1

Network 2

Network 3

Temperature Pain Report

Network 4

Study 1 Summary

Pain is generated by a combination of independent networks

- Increases with temp + increases predict pain (e.g. SII, “salience network”)
- Decreases with temp + decreases predict pain (e.g. DMN)
- Suppression effects / negative mediators (DMPFC, mOFC)
- Pain-related without responding to temperature (e.g. DLPFC, DMPFC, OFC)

Mediation can help identify regions that link objective stimulus with subjective response

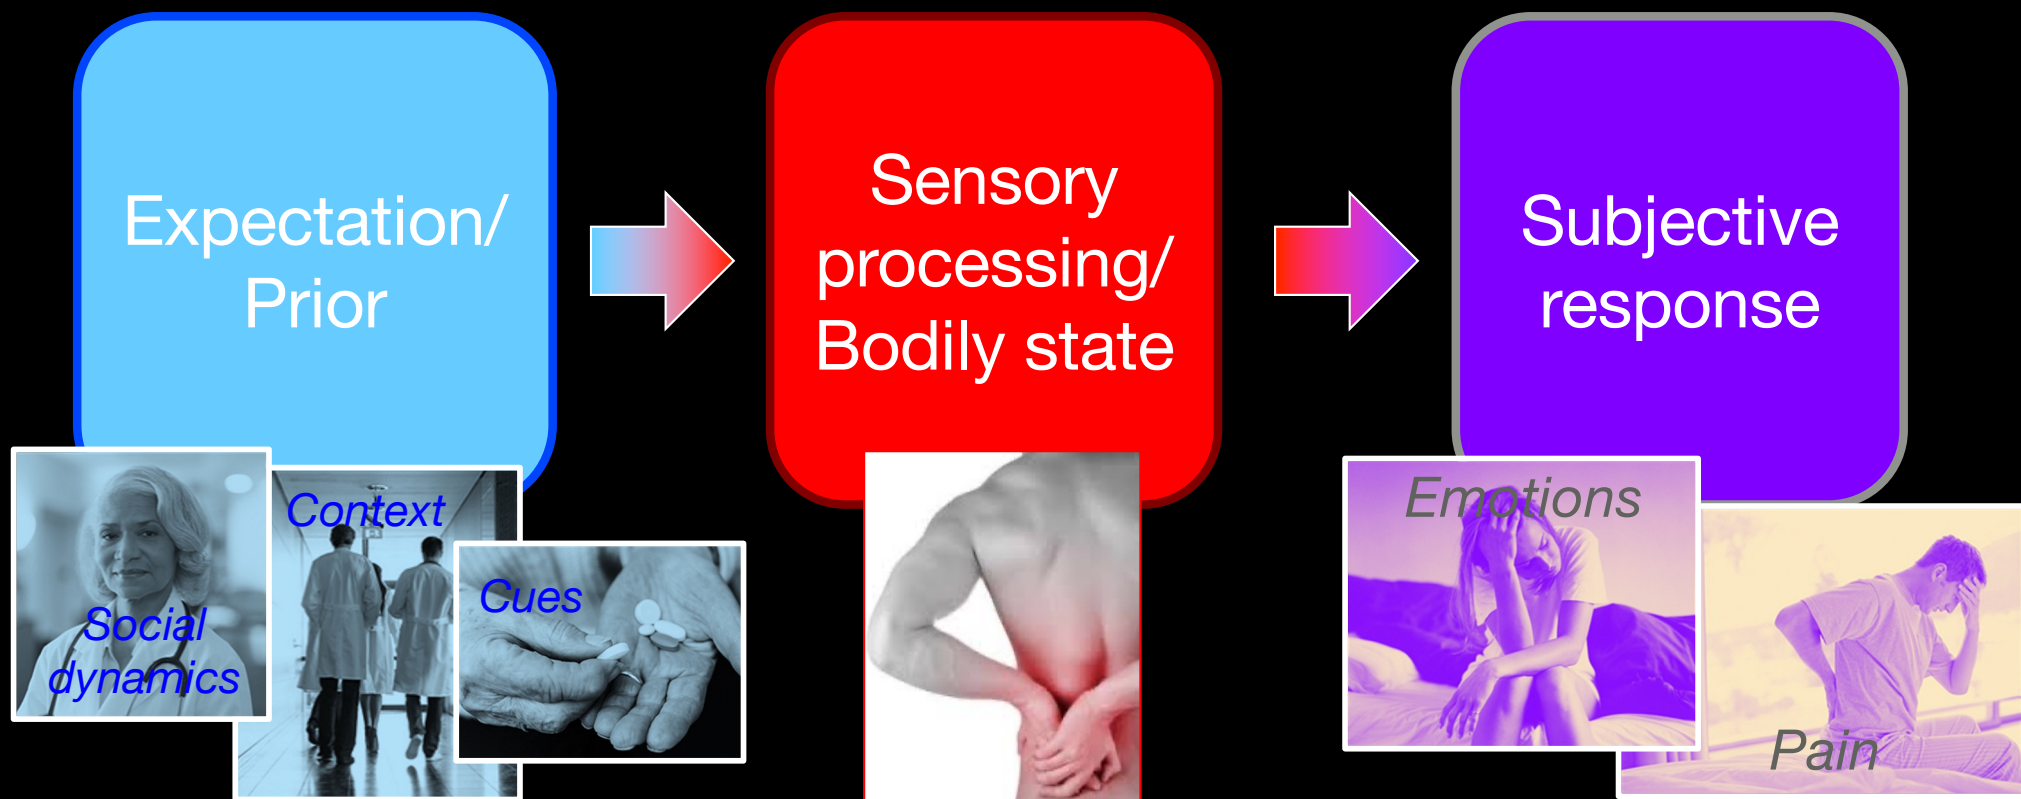

Study 2

Which brain pathways mediate expectancy effects on pain?

Atlas, Bolger, Lindquist, and Wager, 2010, JNeurosci

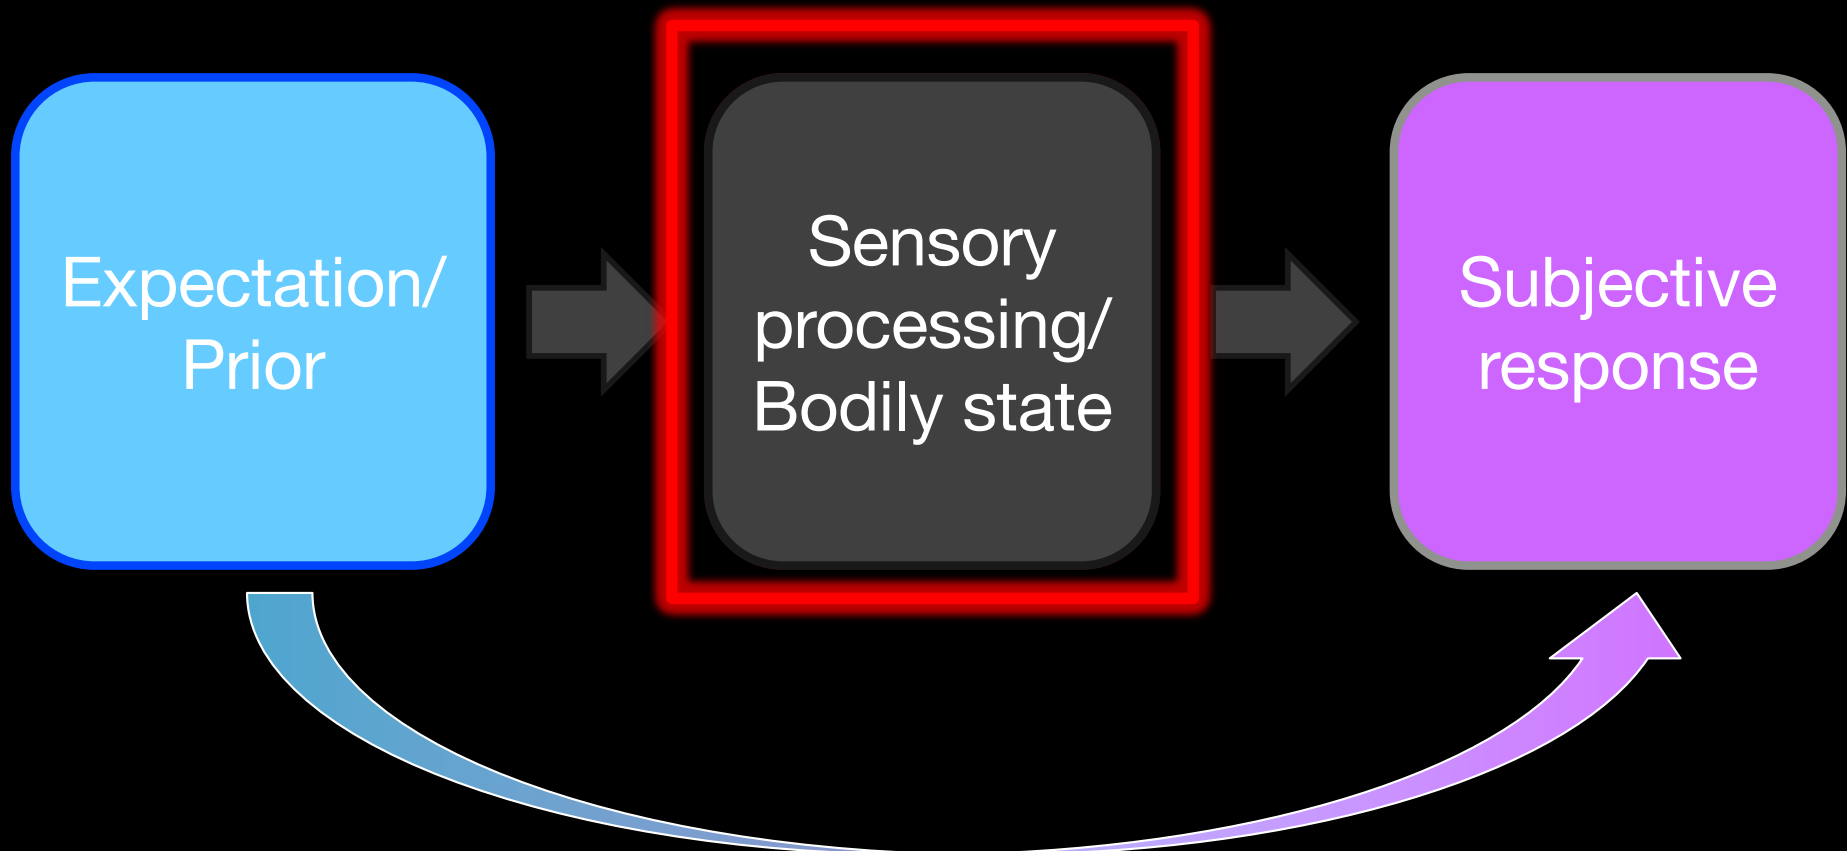

Working model

Report biases/ Changes in decision-making?

*(Hrobjartsson & Gotzsche 2001/04;
Allan & Siegel 2002; Clark 2003)*

“Neurologic pain signature”

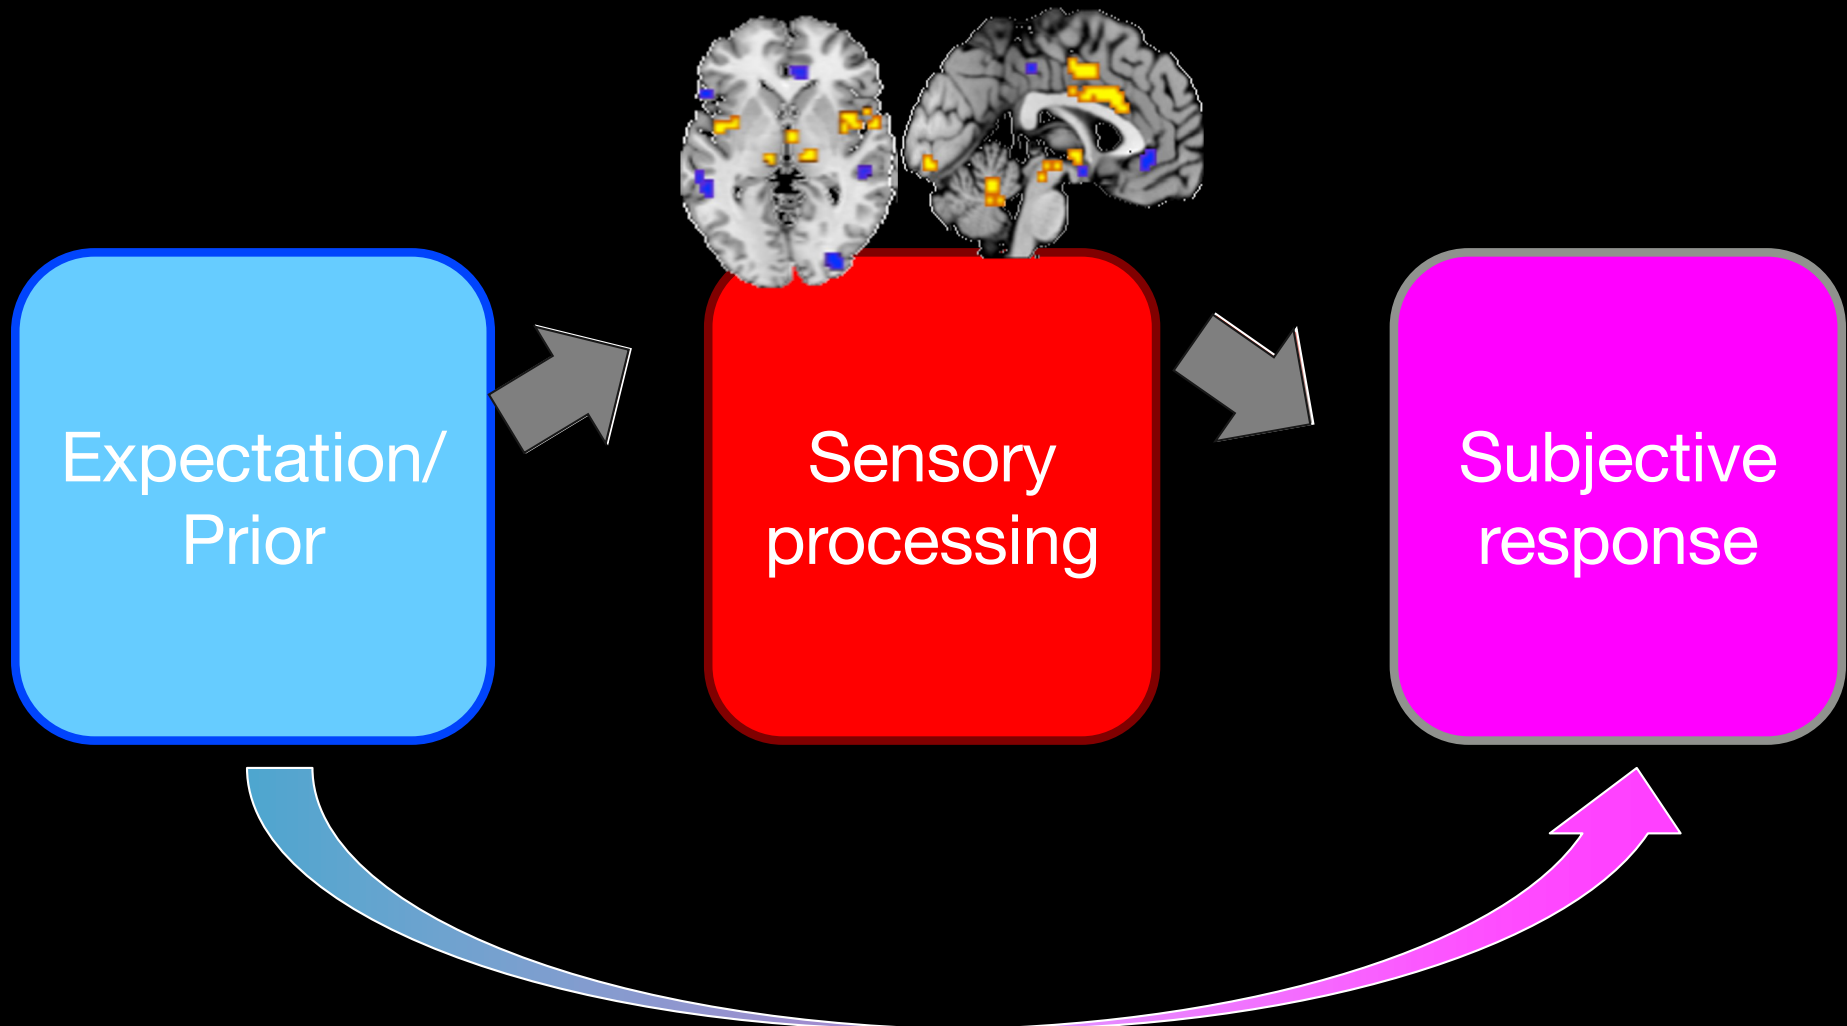

- *Predicts pain in new subjects, in new scanners, in new studies*
- *Highly specific to pain*

Wager, Atlas, et al. (2013), *NEJM*

Do expectations cause changes in pain processing network, and does that give rise to changes in subjective pain?

Our approach

Expectancy

Reported
pain

We used *multi-level mediation* to assess dynamic relationship between trial-by-trial cue-based expectancy, brain activity, and reported pain

Atlas, Bolger, Lindquist, and Wager, 2010, JNeurosci

Expectancy effects on subjective pain

Pain calibration

RESULTS

Atlas et al., 2010, *JNeurosci*

c) Cue-based expectations shape pain

a) Expectations shape responses to heat (HM > LM)

b) Responses predict pain, controlling for cue

c-c') Pain network responses mediate cue effects on pain.

Neurologic Pain Signature (NPS)

Atlas et al., 2010, *JNeurosci*

Wager, Atlas, et al., 2013, *NEJM*

Study 2 summary

Cue-based expectancy effects on pain are mediated by pain-related regions

- Voxelwise analyses (Atlas et al., 2010) reveal other mediating networks as well

Mediation analysis can identify mediators of IV effects on DV

Mediation for effective connectivity

- Cues \rightarrow VS and OFC \rightarrow Pain-related mediators

Summary

Why use multilevel mediation:

1. Relate independent and dependent variables
2. Test hypothesized pathways
3. Relate individual differences to within-subjects pathway strength

Summary

Consider inferences:

Stronger inferences about directionality if variables are separated in time

- E.g. Cue -> Anticipation -> Pain -> Report

Strongest inference when you can experimentally manipulate X AND M (e.g. using TMS)

- see Holland, Rubin

Moderation

Mediation: does [M] explain some or all of the relationship btwn [X] and [Y]?

Moderation: does the level of [M] influence the relationship btwn [X] and [Y]?

Full model, with mediator and moderator

$$m = i_m + ax + e_m$$

$$y = i_y + bm + c'x + d(mo*x) + e'_y$$

Moderator: Level of mo predicts x-y covariance

Mo*x interaction

Should center x and y to reduce correlation
between moderation and x effects
